Assignment 6
Theoretical Neuroscience

Loic Matthey (loic.matthey@gatsby.ucl.ac.uk)
Ritwik Niyogi (Ritwik.Niyogi@gatsby.ucl.ac.uk)

Due 19 November, 2010

1. **The Hodgkin-Huxley neuron**

   Numerically integrate the Hodgkin-Huxley equations with matlab. Best idea is to use the Matlab `ode45` function. The equations are:

$$
\begin{aligned}
C\frac{dV}{dt} &= -\overline{g}_{Na} m^3 h (V - E_{Na}) - \overline{g}_K n^4 (V - E_K) - \overline{g}_L (V - E_L) + I_{stim} && (1)\\
\frac{dx}{dt} &= \alpha_x (1 - x) - \beta_x x \qquad \text{where } x \text{ is } m, n \text{ or } h && (2)\\
\alpha_n(V) &= 0.01(V + 55)/\left[1 - \exp(-(V + 55)/10)\right] && (3)\\
\beta_n(V) &= 0.125 \exp(-(V + 65)/80) && (4)\\
\alpha_m(V) &= 0.1(V + 40)/\left[1 - \exp(-(V + 40)/10)\right] && (5)\\
\beta_m(V) &= 4 \exp(-(V + 65)/18) && (6)\\
\alpha_h(V) &= 0.07 \exp(-(V + 65)/20) && (7)\\
\beta_h(V) &= 1/\left[\exp(-(V + 35)/10) + 1\right] && (8)
\end{aligned}
$$

   Let $C = 10\,\mathrm{nF/mm^2}, \overline{g}_L = .003\,\mathrm{mS/mm^2}, \overline{g}_K = 0.36\,\mathrm{mS/mm^2}, \overline{g}_{Na} = 1.2\,\mathrm{mS/mm^2}, E_K = -77\,\mathrm{mV}, E_L = -54.387\,\mathrm{mV},$ and $E_{Na} = 50\,\mathrm{mV}$. Use an integration time step of 0.1 ms.

   Remember, F/S = Farad/Siemens = 1 second.

   (a) Run the simulations with I_{stim} = 200 nA/mm. Plot the membrane potential (V) and gating variables (m, h, and n) versus time.

   (b) Write down expressions for the equilibrium values of the gating variables (m_∞, h_∞, and n_∞), and plot them versus voltage.

   (c) Plot the firing rate versus I_{stim}, up to a firing rate of 50 Hz. The firing rate should jump suddenly from zero to a non-zero value. This is called a type II behaviour. Type I behaviour is when the firing rate begins at zero and increases continuously without any jumps.

   (d) What happens to the plot of firing rate versus I_{stim} as you decrease $\overline{g}_K$?

   (e) Spikes are initiated at the axon hillock, where the axon meets the soma. This is because $\overline{g}_{Na}$ is very high there. What happens to the plot of firing rate versus I_{stim} as you increase $\overline{g}_{Na}$?

2. **The linear integrate and fire neuron**

   An approximate treatment of spiking neurons is to think of them as passively integrating input and, when the voltage crosses threshold, emitting a spike. This leads to the linear integrate and fire neuron (sometimes called the leaky integrate and fire neuron, and often abbreviated LIF), which obeys the equation

$$C\frac{dV}{dt} = -g_L(V - \mathcal{E}_L) + I_0 \,.$$

   This is just the "linear integrate" part. To incorporate spikes, when the voltage gets to threshold (V_t), the neuron emits a spike and the voltage is reset to rest (V_r).

   (a) Compute the firing rate of the neuron as a function of I_0. This firing rate will be parameterized by three numbers: $\mathcal{E}_L$, V_t, and V_r.
   Hint #1: The firing rate is the inverse of the time it takes to go from V_r to V_t.
   Hint # 2: Changing variables, and defining new quantities, almost always makes life easier. For example, you might let $v = V - \mathcal{E}_L$ and define $V_0 \equiv I_0/g_L$ and $\tau \equiv C/g_L$.

   (b) Let $I(t) = g_L V_0 \sin(\omega t)$, $V_r = \mathcal{E}_L$, $V_t = \mathcal{E}_L + \Delta V$, and define $C/g_L \equiv \tau$. Show that the neuron will *not* spike if $V_0 < (1 + \tau^2\omega^2)^{1/2}\Delta V$.

3. **Nullclines.** Consider a simplified Hodgkin-Huxley type model,

$$\begin{aligned}
\tau\frac{dV}{dt} &= -(V - \mathcal{E}_L) - hm(V)V \\
\tau_h\frac{dh}{dt} &= h_\infty(V) - h \\
m(V) &= \frac{1}{1 + \exp(-(V - V_t)/\epsilon_m)} \\
h_\infty(V) &= \frac{1}{1 + \exp(+(V - V_h)/\epsilon_h)}
\end{aligned}$$

   with parameters

$$\begin{aligned}
\mathcal{E}_L &= -65 \text{ mV} \\
V_t &= -50 \text{ mV} \\
\epsilon_h &= 10 \text{ mV} \\
\epsilon_m &\ll 1 \text{ mV}\,.
\end{aligned}$$

   The remaining parameter, V_h, will be specified as needed (it will take on a range of values).

   (a) Sketch the nullclines in V-h space for $V_h = -60, -50$ and -40 mV. Put voltage on the x-axis and h on the y-axis. For each equilibrium, tell us whether it is stable or unstable, or hard to tell without a detailed stability analysis.

   (b) Find the condition on V_h that guarantees more than one equilibrium.

   (c) For a value of V_h such that there is more than one equilibrium, sketch the trajectories starting at V slightly greater than V_t and $h = 1$.

   (d) Show (graphically) that the amplitude of the spike is an increasing function of τ_h.
